Overview

Anti-islanding prevention is essential for maintaining grid stability and ensuring energy storage systems operate efficiently while complying with grid codes. What is anti-islanding protection?

An inverter connected to a grid and outfitted with anti-islanding protection is designed to disconnect the electrical supply from the grid if a blackout occurs. Anti-islanding protection is a way for the inverter to sense when the power grid is struggling or has failed. It then stops feeding power back to the grid.

How do inverter-based DERs protect against islanding?

Inverter-based DERs, such as PV and storage systems, feature built-in protection mechanisms that detect when they have become islanded from the distribution grid. Inverters have traditionally used a number of anti-islanding protection methods that have been classified as either passive or active.

What is islanding in a single-phase grid connected inverter?

In some cases, islanding is intentional. When this occurs, the inverter detects the grid event and automatically disconnects itself from the grid, creating an island intentionally. The single-phase grid connected inverter is then forced to push power to the local circuit. This method is used as a backup power generation system.

Can distributed energy resources (DERs) protect against unintentional islands?

Northbrook, IL. Due to equipment and personnel safety dimensions, some jurisdictions apply additional methods to ensure that distributed energy resources (DERs) do not island. This appendix summarizes these concerns and supplementary anti-islanding protection strategies. Many methods can be used to protect against unintentional islands.

Do DERs need anti-islanding protection?

Anti-islanding protection is required for all DERs that comply with IEEE Std

1547-2018 and UL 1741, Standard for Safety for Inverters, Converters, Controllers, and Interconnection System Equipment for Use with Distributed Energy Resources.

What methods can be used to provide unintentional islanding protection?

18 IEEE Std 1547-2018 notes that additional methods may be used to provide unintentional islanding protection, such as direct transfer trip or radio or cellular communications channels; however, type testing those methods was considered out of scope of the standard. Figure 3.
